

</talentlabs>

CHAPTER 1

Intro to Python

</talentlabs>

AGENDA

- Curriculum
- Intro to Python and Tools
- Trying Python
- Data Types
- Your First Python
Python Program

Curriculum

Curriculum

Part 1

Python Basics (6 chapters)

Tools (Online code platforms, Editors)
Running Python Programs
Expressions
Data Types
Flow Control
Functions
Lists & Objects
Building Games: Number Guessing
Game and Tic-Tac-Toe

Part 2

Automation with Python (5 classes)

Handling Files and Documents
Email Automation
PDFs and Excls
Data Fetching from API

What is Python?

What is Python?

- Python is one of the **most popular** programming language and one of the **easiest to learn** language
- Python is popular for
 - **data analysis**, machine learning
 - **scripting and automation**
 - **server-side programming**
 - **beginners**

Major Python Versions

- Python Versions: 2 and 3
- **We are using Python 3** in this course
- **Python 2 is being abandoned** by most of the major tech companies like Google

How To Get Started?

Python Runtime

Most of the Windows 10 PC should have that included.

If not, you can download and install at <https://www.python.org/downloads/>

IDE(Integrated Development Environment)/ Code Editor

The editor and debugging tool for most programming languages

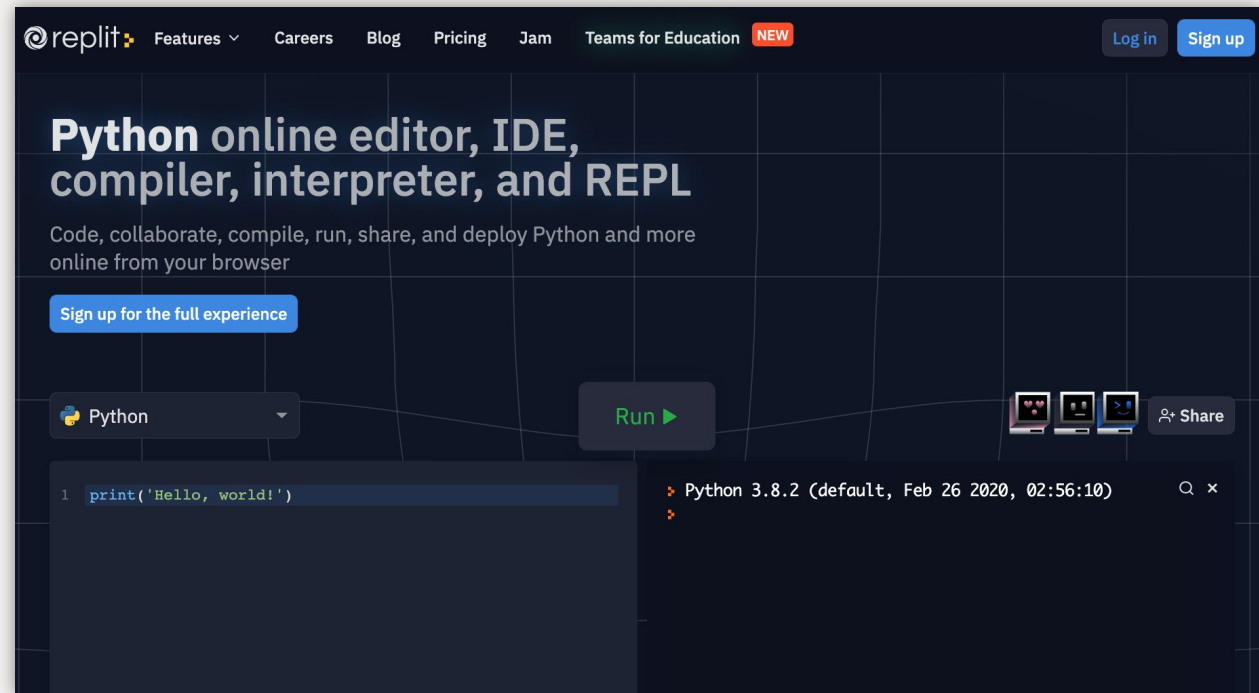

Please download and install at: <https://code.visualstudio.com/>

Handy Way of Testing & Running Python

Online Python Runtime

There are a number of online python runtime. We suggest to try with <https://replit.com/languages/python3>

Trying Python

Print Functions

- To print out something as result in the “console”

```
print([value that you want to print])
```

Doing Calculation with Python

- Just like what you learn in Math

$$2 + 2$$

$$3 * 2$$

(in computer multiply is denoted by * instead of x)

$$2 + 3 * 4$$

$$(2 + 3) * 4$$

Doing Calculation on Text (aka String)

- Create string using double quote or single quote
 - "Hello World"
 - 'Hello World'

- Adding Strings together?
 - "Hello " + "World"
 - "Hello " + "World" * 3

What are Data Types?

Data Storage (Variable)

- Computers are all about **passing data** around and **storing data**
- Computer is essentially a **data processing device**

How Do We Represent Them in Code?

- Using variables
- Variables are like water buckets

50

X

Apple

Y

3.4

Z

How Do We Represent Them in Code?

- Using variables
 - Variables are like water buckets
- $x = 50$
 - $y = \text{"apple"}$
 - $z = 3.4$

50

X

Apple

Y

3.4

Z

How Do We Represent Them in Code?

- So we need to customize the buckets
- Small bucket for smaller data

X
2 characters
(Wasted 4 characters)

Y
5 characters
(Wasted 1 characters)

Z
3 characters
(Wasted 3 characters)

Bucket Size
= 6 characters

So we need data types to optimize storage (one of the reasons only)

- So we need to customize the buckets
- Small bucket for smaller data

List of Data Types

How Many Types of Bucket We Have in Python?

Your First Python Program

input () function

- To collect/receive user input
- For building an interactive program

```
1 print("What is your name?")
2 username = input()
3 print("Hello " + username)
```

Converting User Input

- User Input are **always a string**, even if they are inputting a number
- We need to **convert** it if we want a number
- You can use `str()`, `float()`, and `int()` to convert between text, decimals and integers

```
1 print("What is your age?")
2 age = input()
3 age_next_year = age + 1
4 print("You will be " + age_next_year + " next year")
```

Wrong Handling

```
1 print("What is your age?")
2 age = input()
3 age_next_year = int(age) + 1
4 print("You will be " + str(age_next_year) + " next year")
```

Correct Handling

len()

- Get the length of a value

```
1 print(len('26'))    # print 2
2 print(len('Hello')) # print 5
```
